Today: deploy-kit 1.x, in production (spec/v1 chapter 55)
Project CI
validate the Intent; build, pin images
compose
TypeScript compiler renders the estate once
ghcr
one signed artifact per Project, by digest
estate repository
a commit moves the Project's digest pin
Flux, then Flagger
pull, verify, apply; switch, Release Gate
Designed: estate-kit, accepted records 2, 9, 17, 25, 58, 74, 75
Project CI
validate; build once, register the digests
deploy service, Rust
compose; dry run twice, as a non-writing identity
Vault Transit
signs the render; the key stays in Vault
ghcr
render/<project>:<env>, moved under a Lease
Flux, then Flagger
pull, verify, apply; gate from cluster state
Likely future direction: estate-kit research note, not decided
Project CI, any forge
through a Forge port; watches until the end
Conductor
compose, dry run, sign; streams events back
own OCI registry
Environment tag; no ghcr machine token
Applier, own process
replaces Flux: pull, verify, apply in steps
Flagger
driven as one step; Release Gate answers
event stream, both ways
per-object status
